Recitation 8

CTC Decoding & Beam Search

Soumya Vadlamannati, Amala Deshmukh
Sequence to Sequence Modeling

Order-Synchronous, Not Time-Synchronous Output

1. Training -> we already know how to do that
2. Testing -> “Decoding” or “obtaining an output from a sequence-to-sequence network”
A key decoding problem

- Consider a problem where the output symbols are characters
- We have a decode: RRROOOOOD
- Is this the merged symbol sequence ROD or ROOD?

How to distinguish between an extended symbol and repetitions of a symbol?
A key decoding problem

Solution: Introduce an explicit extra symbol which serves to separate discrete versions of a symbol

- A “blank” (represented by “-”)
- $\text{RRR---OO---DDD} = \text{ROD}$
- $\text{RR-R---OO---D-DD} = \text{RRODD}$
- $\text{R-R-R---O-ODD-DDDD-D} = \text{RRROODDD}$

The symbol set recognized by the network must now include the extra blank symbol

- Which too must be trained
The modified forward output

Note the extra “blank” at the output
Composing graph for training

Train as before!

- With blanks
- Note: a row of blanks between any two symbols
- Also blanks at the very beginning and the very end
CTC: Connectionist Temporal Classification

- The overall framework we saw is referred to as CTC
  - Applies when “duplicating” labels at the output is considered acceptable, and when output sequence length < input sequence length
Returning to the decoding problem

How to decode at test time?

- Greedy decode -> choose symbol with highest probability at each time step and merge
  - Sub-optimal decode which finds most likely synchronous output sequence

- Objective of decoding -> Most likely asynchronous symbol sequence
  - Find all decodings and pick the most likely decode!
  - Unfortunately, explicit computation of this will require evaluation of an exponential number of symbol sequences
  - Solution: Organize all possible symbol sequences as a (semi)tree
Hypothesis semi-tree

- The semi tree of hypotheses (assuming only 3 symbols in the vocabulary)
- Every symbol connects to every symbol other than itself
- It also connects to a blank, which connects to every symbol including itself
- The simple structure repeats recursively
- Each node represents a unique symbol sequence!
Decoding graph for the tree

- The figure to the left is the tree, drawn in a vertical line.
- The graph is just the tree unrolled over time.
- The alpha at final time represents the full forward score for a unique symbol sequence.
- Select the symbol sequence with the largest alpha.
Pruning

- This is the “theoretically correct” CTC decoder
- In practice, the graph gets exponentially large very quickly
- To prevent this pruning strategies are employed to keep the graph (and computation) manageable

Beam Search

- **PathScore**: array of scores for paths ending with symbols
- **BlankPathScore**: array of scores for paths ending with blanks
- **SymbolSet**: A list of symbols *not* including the blank
Global PathScore = [], BlankPathScore = []

# First time instant: Initialize paths with each of the symbols, # including blank, using score at time t=1

Find nodes on "symbol" rows with scores above cutoff and add them to the "active" list
Consider this instant

Effectively prune out nodes on “symbol” rows with scores below cutoff. They will subsequently not contribute to the computation.

Retain nodes on “symbol” rows with scores above cutoff.
Effectively prune out nodes on “symbol” rows with scores below cutoff. They will subsequently not contribute to the computation.

Consider this instant. Retain nodes on “symbol” rows with scores above cutoff.
Global PathScore, BlankPathScore

function Prune(PathsWithTerminalBlank, PathsWithTerminalSymbol, BlankPathScore, PathScore, BeamWidth)
    PrunedBlankPathScore = []
    PrunedPathScore = []
    # First gather all the relevant scores
    i = 1
    for p in PathsWithTerminalBlank
        scorelist[i] = BlankPathScore[p]
        i++
    end
    for p in PathsWithTerminalSymbol
        scorelist[i] = PathScore[p]
        i++
    end
    # Sort and find cutoff score that retains exactly BeamWidth paths
    sort(scorelist)  # In decreasing order
    cutoff = BeamWidth < length(scorelist) ? scorelist[BeamWidth] : scorelist[end]
    PrunedPathsWithTerminalBlank = {}
    for p in PathsWithTerminalBlank
        if BlankPathScore[p] >= cutoff
            PrunedPathsWithTerminalBlank += p  # Set addition
            PrunedBlankPathScore[p] = BlankPathScore[p]

        end
    end
    return PrunedPathsWithTerminalBlank, PrunedPathsWithTerminalSymbol, PrunedBlankPathScore, PrunedPathScore

The overall effect of these steps:
BEAM SEARCH

Global PathScore = [], BlankPathScore = []

# First time instant: Initialize paths with each of the symbols, # including blank, using score at time t=1
NewPathsWithTerminalBlank, NewPathsWithTerminalSymbol, NewBlankPathScore, NewPathScore = InitializePaths(SymbolSet, y[:,0])

# Subsequent time steps
for t = 1:T
    # Prune the collection down to the BeamWidth
    PathsWithTerminalBlank, PathsWithTerminalSymbol, PathScore, BlankPathScore = Prune(NewPathsWithTerminalBlank, NewPathsWithTerminalSymbol, y[:,t])

    # First extend paths by a blank
    NewPathsWithTerminalBlank, NewBlankPathScore = ExtendWithBlank(PathsWithTerminalBlank, PathsWithTerminalSymbol, y[:,t])

    # Next extend paths by a symbol
    NewPathsWithTerminalSymbol, NewPathScore = ExtendWithSymbol(PathsWithTerminalBlank, PathsWithTerminalSymbol, SymbolSet, y[:,t])

end

# Merge identical paths differing only by the final blank
MergedPaths, FinalPathScore = MergeIdenticalPaths(NewPathsWithTerminalBlank, NewBlankPathScore, NewPathsWithTerminalSymbol, NewPathScore)

# Pick best path
BestPath = argmax(FinalPathScore)  # Find the path with the best score

Why is the pruning here and not at the end of the loop? Because we don’t want to prune paths at the final time. This loses information. Instead at the final time we will merge paths that represent the same symbol sequence.
