Recap	Understanding Optimization Issues ₱	GAN Training and Stabilization	Take Aways
Recap			

What did we talk about so far?

- What is a GAN?
- How do GANs work theoretically?
- What kinds of problems can GANs address?

イロト イヨト イヨト イ

Recap	Understanding Optimization Issues ₱	GAN Training and Stabilization	Take Aways
Recap			

What is a GAN?

- Train a generator to produce samples from a target distribution
- Discriminator guides generator
- Generator and Discriminator are trained adversarially

CMU

Recap	Understanding Optimization Issues ₱	GAN Training and Stabilization	Take Aways
Recap			

How do GANs work theoretically?

- Discriminator calculates a divergence between generated and target distributions
- Generator tries to minimize the divergence

イロト イヨト イヨト イヨト

How can you build one yourself?

- Define a generator network that takes random inputs and produces an image
- Define a discriminator network that takes images and produces a scalar
 - Draw a random batch of Z from prior
 - Draw a random batch of X from data
 - Gradient descent generator weights w.r.t. generator loss
 - Gradient descent discriminator weights w.r.t. discriminator loss
- See recitations and tutorials for details

< ロ > < 回 > < 回 > < 回 > < 回 >

Recap	Understanding Optimization Issues F	GAN Training and Stabilization	Take Aways
Recap			

What kinds of problems can GANs address?

- Generation
- Conditional Generation
- Clustering
- Semi-supervised Learning
- Representation Learning
- Translation

Any traditional discriminative task can be approached with generative models

イロト イヨト イヨト イヨト

CMU

Recap	Understanding Optimization Issues ₱	GAN Training and Stabilization	Take Aways
Recap			

What is a discriminator?

- A new type of loss function
- Measures the divergence between distributions, not between examples
- Implemented by neural network, has biases of neural network

・ 同 ト ・ ヨ ト ・ ヨ ト

CMU

- Powerful tool for generative modeling
- Lots of potential
- Limited by pragmatic issues (stability)

イロト イヨト イヨト イヨト

CMU

Common Failures

GAN training can be tricky to diagnose

- "Mode collapse" generates a small subspace but does not cover the entire distribution: https://www.youtube.com/watch?v=ktxhiKhWoEE
- Some errors harder to describe: https://www.youtube.com/watch?v=D5akt32hsCQ
- Cause can be unclear
 - Discriminator too complicated?
 - Discriminator not complicated enough?

Causes of Optimization Issues

- Simultaneous updates require a careful balance between players
- In general, two player games are not guaranteed to converge to the global optimum
- There is a stationary point but no guarantee of reaching it
- Adversarial optimization is a more general, harder problem than single-player optimization

Simultaneous Updates

Simultaneous Updates

Why are updates simultaneous? Can you just train an optimal discriminator?

- For any given discriminator, the optimal generator outputs $\forall Z : G(Z) = \operatorname{argmax}_X D(X)$
- The optimal discriminator emits 0.5 for all inputs, so isn't useful for training anything
- Optimal discriminator conditional on current generator and vice-versa
- Cannot train generator without training discriminator first
- Therefore generator and discriminator must be trained together

イロン イヨン イヨン イヨン

Simultaneous Updates

Adversarial Balance

What kind of balance is required?

- If discriminator is under-trained, it guides the generator in the wrong direction
- If discriminator is over-trained, it is too "hard" and generator can't make progress
- If generator trains too quickly it will "overshoot" the loss that the discriminator learned

イロト イヨト イヨト イヨト

Simultaneous Updates

Factors Affecting Balance

What affects the balance?

- Different optimizers and learning rates
- Different architectures, depths, and numbers of parameters
- Regularization
- Train D for k_D iterations, train G for k_G iterations, repeat
- Train D and G for dynamic k_D and k_G iterations, depending on some metrics

(日) (四) (三) (三)

イロト イヨト イヨト イヨト

CMU

Adversarial Balance

What does this look like in practice?

- Target distribution is stationary 2D point (green)
- Generator produces a single moving 2D point (blue)
- Discriminator is a 2D linear function, represented by the colored background
- Watch oscillations as generator overshoots discriminator
- https://www.youtube.com/watch?v=ebMei6bYeWw

Even a simple game, Rock, Paper, Scissors, might not converge using alternating updates.

イロト イヨト イヨト イヨト

CMU

- Player A prefers rock by random initialization
- Player B should therefore play only paper
- Player A should play only scissors
- Player B should play only rock

...

GAN Training and Stabilization

CMU

Two-player games

Rock, Paper, Scissors

Why is this so unstable?

$$\mathbb{E}\ell_A = A_R B_S + A_P B_R + A_S B_P$$

Global optimum

- Both players select uniformly w.p. 0.33
- Both players win, lose or draw w.p. 0.33
- Local optimum
 - Say player B plays (*R*, *P*, *S*) w.p. (0.4, 0.3, 0.3)
 - Player A should play (R, P, S) w.p. (0, 1, 0)
 - Player B wins w.p. 0.4
- What happens if you use gradient descent? https://www.youtube.com/watch?v=JmON4SOk104

converge to it

- Gradients can circle or point away from the minima
- Stationary point may not be stable, no local "well"
- Some degree of smoothness to the discriminator is required
 - Even if discriminator correctly labels generated points 0 and real points 1
 - Does not mean the gradient of the discriminator is in the right direction
 - Does not mean area around generated points is 0 and area around real points is 1

Ongoing research into "best" GAN

- Likely no silver-bullet
- Combinations of techniques work well
- Getting better every year

• • • • • • • • • • • •

CMU

GAN Training Techniques

We will discuss a sample of training/stabilization techniques

- Will not cover every idea people have tried
- Goal is to understand the types of techniques and research
- Will cover some interesting or historical ideas that aren't that great
- I am not endorsing all of the following techniques

GAN Training Techniques

- Unrolled Generative Adversarial Networks
- Gradient descent is locally stable
- DRAGAN
- Numerics of GANs
- Improved Techniques for GANs
- Least-Squares GAN

- Instance Noise
- EBGAN
- WGAN
- WGAN-GP
- Spectral Normalized GAN

イロト イヨト イヨト イヨト

- Fisher GAN
- LapGAN
- ProgGAN

CMU

Unrolled Generative Adversarial Networks

Unrolled Generative Adversarial Networks

Optimize future loss, not current loss [MPPS16]

- Calculate the discriminator after a few SGD steps
- Find the generator that has the best loss on the future discriminator
- Differentiate through gradient descent

イロト イヨト イヨト イヨト

Think of it like chess. Make move that gives the best result after the opponent's move, not the best immediate reward.

$$\theta_D^0 = \theta_D$$

$$\theta_D^{k+1} = \theta_D^k + \eta^k \frac{\partial f(\theta_G, \theta_D^k)}{\partial \theta_D^k}$$
$$f_{\mathcal{K}}(\theta_G, \theta_D) = f(\theta_G, \theta_D^{\mathcal{K}}(\theta_G, \theta_D))$$

GANs

Unrolled Generative Adversarial Networks

UGAN Results

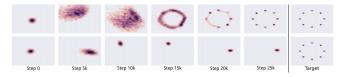

Figure 2: Unrolling the discriminator stabilizes GAN training on a toy 2D mixture of Gaussians dataset. Columns show a heatmap of the generator distribution after increasing numbers of training teps. The final column shows the data distribution. The top row shows training for a GAN with 10 unrolling steps. Its generator quickly spreads out and converges to the target distribution. The bottom row shows standard GAN training. The generator rotates through the modes of the data distribution. It never converges to a fixed distribution, and only ever assigns significant probability mass to a single data mode at once.

CMU

< ロ > < 回 > < 回 > < 回 > < 回 >

Gradient descent GAN optimization is locally stable

Gradient descent GAN optimization is locally stable

Minimize the original objective as well as the gradient of the objective [NK17]

- Gradient of the discriminator is how much discriminator can improve
- If generator makes improvement, but discriminator gradient is large, discriminator can undo that improvement
- If generator makes improvement in a way that the discriminator gradient is zero, discriminator cannot undo that improvement

$$\ell_G = \ell_{G,0} + \eta \left\| \nabla \ell_D \right\|^2$$

(日) (四) (三) (三)

How to train your DRAGAN

How to train your DRAGAN

Minimize the norm of the gradient in a region around real data [KAHK17]

- Minimize the norm of the gradient makes a function smoother
- Smooth in a random region around real data to smooth the discriminator

$$\lambda \mathbb{E}_{X,\epsilon} \max(0, \|\nabla D(X+\epsilon)\|^2 - k)$$

イロト イ団ト イヨト イヨト

The Numerics of GANs

The Numerics of GANs

GANs define a vector field [MNG17]

- Consider the joint field of generator and discriminator parameters
- Stationary points are where the gradient of each player w.r.t. its own parameters is 0
- Find these regions by minimizing the norm of the gradient of each player
- Regularization parameter balances between adversarial objective and consensus objective

$$L = L_0 + \lambda \left\| \nabla L_0 \right\|_2^2$$

GANS

< ロ > < 回 > < 回 > < 回 > < 回 >

Why "consensus"?

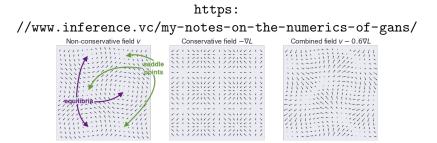

- Generator tries to minimize discriminator gradients as well as its own
- Discriminator tries to minimize generator gradients as well as its own
- Mutual de-escalation
- Encourages towards minima, maxima, and saddle points
- Small regularization parameter so hopefully finds the minima

< ロ > < 回 > < 回 > < 回 > < 回 >

The Numerics of GANs

Vector Fields

CMU

Improved Techniques for Training GANs

Improved Techniques for Training GANs

A collection of interesting techniques and experiments

- Feature matching
- Minibatch discrimination
- Historical averaging
- One-sided label smoothing
- Virtual batch normalization

イロト イ団ト イヨト イヨト

イロン イ団 と イヨン イヨン

CMU

Improved Techniques for Training GANs

Feature Matching

Statistics of generated images should match statistics of real images

- Discriminator produces multidimensional output, a "statistic" of the data
- Generator trained to minimize L₂ between real and generated data
- Discriminator trained to maximize L₂ between real and generated data

 $\|\mathbb{E}_X D(X) - \mathbb{E}_Z D(G(Z))\|_2^2$

Improved Techniques for Training GANs

Minibatch Discrimination

Discriminator can look at multiple inputs at once and decide if those inputs come from the real or generated distribution

- GANs frequently collapse to a single point
- Discriminator needs to differentiate between two distributions
- Easier task if looking at multiple samples

イロト イ団ト イヨト イヨト

イロト イ団ト イヨト イヨト

Take Aways

CMU

Improved Techniques for Training GANs

Historical Averaging

Dampen oscillations by encouraging updates to converge to a mean

- GANs frequently create a cycle or experience oscillations
- Add a term to reduce oscillations that encourages the current parameters to be near a moving average of the parameters

$$\left\|\theta - \frac{1}{t}\sum_{i}^{t}\theta_{i}\right\|_{2}^{2}$$

Improved Techniques for Training GANs

One-sided label smoothing

Don't over-penalize generated images

- Label smoothing is a common and easy technique that improves performance across many domains
 - Sigmoid tries hard to saturate to 0 or 1 but can never quite reach that goal
 - Provide targets that are ϵ or $1-\epsilon$ so the sigmoid doesn't saturate and overtrain
- Experimentally, smooth the real targets but do not smooth the generated targets when training the discriminator

Improved Techniques for Training GANs

Virtual Batch Normalization

Use batch normalization to accelerate convergence

- Batch normalization accelerates convergence
- However, hard to apply in an adversarial setting
- Collect statistics on a fixed batch of real data and use to normalize other data

イロト イ団ト イヨト イヨト

Least-Squares GAN

Least-Squares GAN

Use an L_2 loss instead of cross-entropy [MLX⁺16]

- Generator tries to minimize L_2 loss $||a D(G(Z))||_2^2$
- Generator tries to minimize L_2 loss $\|b - D(G(Z))\|_2^2 + \|c - D(G(Z))\|_2^2$
- For example, a = 1, b = 0, c = 1

Less squashing and large values than cross-entropy

GANS

イロト イポト イヨト イヨト

Amortised MAP Inference for Image Super-Resolution

Amortised MAP Inference for Image Super-Resolution

Part of a larger paper with several modifications and experiments [SCT⁺16]

- "Instance Noise"
- Add noise to generated and real images
- Smooth the function learned by the discriminator

Simple and effective

イロト イ団ト イヨト イヨト

イロト イロト イヨト イヨト

CMU

Energy-based Generative Adversarial Network

Energy-based Generative Adversarial Network

Simplify the loss function, removing powers and exponents [ZML16]

- No longer easily described using JS divergence or something similar
- Greatly simplified and linear
- Gradients are neither squashed nor explode

$$L_D = \mathbb{E}_X D(X) + \mathbb{E}_Z \left[m - D(G(Z)) \right]^+$$

$$L_G = D(G(z))$$

- Solve Wasserstein "earth mover" distance
- Provide a smoother gradient
- Constrain Lipschitz of discriminator to 1
- Harder to overtrain discriminator

 $L_D = \mathbb{E}_X D(X) - \mathbb{E}_Z D(G(Z))$ $L_G = \mathbb{E}_Z D(G(Z))$

・ロト ・四ト ・ヨト ・ヨト

CMU

Wasserstein Distance

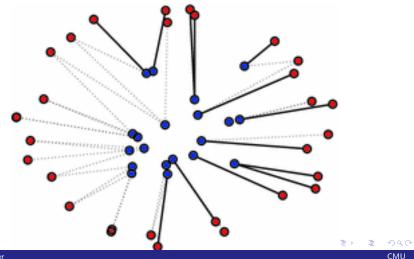

The total $\sum \text{mass} \times \text{distance}$ required to transform one distribution to another.

- Intuitive, symmetric measure of divergence
- Hard to calculate because requires solving "optimal transport"
- You have some distribution of products at some warehouses and you need to make some other distribution of products at those warehouses
- \blacksquare Move the products to the target distribution minimizing $\sum mass \times distance$
- Creating the optimal "transport plan" can be NP-hard

イロト イボト イヨト イヨト

Optimal Transport

Benjamin Striner

GANs

(a)

CMU

Wasserstein GAN

KL Example

$$\mathcal{KL}(p\|q) = \int_{x} p(x) \log \frac{p(x)}{q(x)}$$

- Real data is a point mass at 0
- Generated data is a point mass at θ

If
$$heta
eq 0$$
, $p(0)\lograc{p(0)}{q(0)}=1rac{1}{0}=\infty$

- If $\theta = 0$, $1 \log \frac{1}{1} = 0$
- **Not differentiable w.r.t.** θ

Calculate the average distribution and calculate the average KL to the average.

$$m(x) = \frac{p(x) + q(x)}{2}$$
$$JS(p||q)$$

(a)

CMU

- Real data is a point mass at 0
- \blacksquare Generated data is a point mass at θ

If
$$\theta \neq 0$$
, $\frac{1}{2} \left[1 \log \frac{1}{0.5} + 1 \log \frac{1}{0.5} \right] = \log 4$
If $\theta = 0$, $\frac{1}{2} \left[1 \log \frac{1}{1} + 1 \log \frac{1}{1} \right] = 0$

Not differentiable w.r.t. θ

Wasserstein Example

Calculate the mass times the distance in one dimension

- Real data is a point mass at 0
- \blacksquare Generated data is a point mass at θ
- EM is |θ|
- **Differentiable w.r.t.** θ !

イロト イ団ト イヨト イヨト

EM v JS Visualized

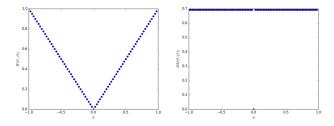

Figure 1: These plots show $\rho(\mathbb{P}_{\theta}, \mathbb{P}_0)$ as a function of θ when ρ is the EM distance (left plot) or the JS divergence (right plot). The EM plot is continuous and provides a usable gradient everywhere. The JS plot is not continuous and does not provide a usable gradient.

æ

GAN vs WGAN

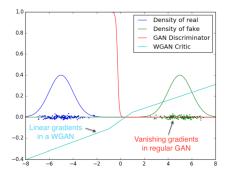

Figure 2: Optimal discriminator and critic when learning to differentiate two Gaussians. As we can see, the discriminator of a minimax GAN saturates and results in vanishing gradients. Our WGAN critic provides very clean gradients on all parts of the space.

CMU

æ

Result showing the EM can be calculated using a dual method

$$\sup_{\phi,\psi} \left(\int_X \phi(x) d\mu(x) + \int_Y \psi(y) d\nu(y) \right)$$

 $\phi(x) - \psi(y) \leq c(x, y)$

(a)

CMU

Provide justification for GAN techniques.

So what's the catch?

Constrain the Lipschitz of an arbitrary function

- Function is nonlinear
- Cannot calculate $\frac{\|D(x) D(y)\|_2}{\|x y\|_2}$ for all pairs
- Just clip the weights to some value
- Constraining the L_{∞} of all weight matrices upper bounds the Lipschitz of the function
- Bound is not great
- In practice, leads to poor discriminators

イロト イ団ト イヨト イヨト

CMU

Improved Training of Wasserstein GAN

Wasserstein GAN-GP

Demonstrate the flaws with gradient clipping [GAA⁺17]

- Propose an alternative method of constraining the Lipschitz
- Lipschitz should be 1 almost everywhere
- Calculate the gradient of *D* at random samples
- Add a penalty of the mean squared distance between the gradient and 1

$$L = \mathbb{E}_{X}(D(X)) - \mathbb{E}_{Z}(D(G(Z)) + \lambda \mathbb{E}_{X'} \left(\left\| \nabla D(X') \right\|_{2} - 1 \right)^{2}$$

Improved Training of Wasserstein GAN

Where to sample?

How to sample?

- Cannot constrain gradient everywhere
- Can only penalize gradient at some samples
- Use samples that are random linear interpolations between real and fake data
- Keeps discriminator smooth over the relevant region

イロト イ団ト イヨト イヨト

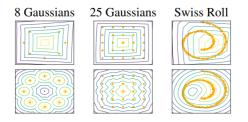

Understanding Optimization Issues

Improved Training of Wasserstein GAN

Discriminator Visualization

(a) Value surfaces of WGAN critics trained to optimality on toy datasets using (top) weight clipping and (bottom) gradient penalty. Critics trained with weight clipping fail to capture higher moments of the data distribution. The 'generator' is held fixed at the real data plus Gaussian noise.

Spectral Normalized GAN

Spectral Normalized GAN

Bound the Lipschitz using the spectral norm of each layer [MKKY18]

 Lipschitz of a single matrix multiplication can be calculated using a power iteration

$$\sup_{x} \frac{\|xA\|_{2}}{\|x\|_{2}} = \|A\|_{2}^{*}$$

- Lipschitz of an MLP can be upper bounded by product of each layer
- Constrain each layer by calculating $\hat{W} = \frac{W}{\|W\|_{2}^{*}}$

Fisher IPM does not require constraining the discriminator [MS17]

- Constraint is imposed by the loss function itself
- Difference between D(G(Z)) and D(X) is scaled by D(G(Z)) and D(X)

$$\sup_{f} \frac{\mathbb{E}_{X}D(X) - \mathbb{E}_{Z}D(G(Z))}{\sqrt{\frac{1}{2}\mathbb{E}_{X}D(X)^{2} + \frac{1}{2}\mathbb{E}_{Z}D(G(Z))^{2}}}$$

(a)

CMU

Recap	Understanding Optimization Issues ₱	GAN Training and Stabilization	Take Aways
LapGAN			
LapGAN			

Break image generation into smaller chunks [DCSF15]

- GAN generates small, blurry image
- CGAN sharpens and enlarges image slightly
- Repeat step 2 until desired size
- Separate, small GANs simplify training

< D > < A > < B > < B >

Progressive Growing of GANs

Progressive Growing of GANs

Gradually expand networks, like a curriculum [KALL17]

- Simple generator learns with simple discriminator
- Gradually add layers to generator and discriminator to produce larger images

イロト イ団ト イヨト イヨト

Progressive Growing of GANs

Progessive GAN Visualization

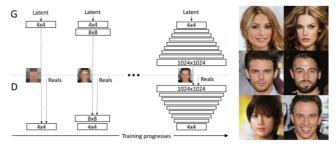

Figure 1: Our training starts with both the generator (G) and discriminator (D) having a low spatial resolution of 4×4 pixels. As the training advances, we incrementally add layers to G and D, thus increasing the spatial resolution of the generated images. All existing layers remain trainable throughout the process. Here $\boxed{N \times N}$ refers to convolutional layers operating on $N \times N$ spatial resolution. This allows stable synthesis in high resolutions and also speeds up training considerably. One the right we show six example images generated using progressive growing at 1024 × 1024.

CMU

Table of Contents

- 2 Understanding Optimization Issues
- **3** GAN Training and Stabilization

4 Take Aways

Common "Gotchas"

- You can only reduce an NP problem into another NP problem
- Unrolling or second gradients are computationally expensive (UGAN, CGAN)
- Sampling-based methods can be unreliable (WGAN-GP)
- Bound-based methods can easily learn poor local optima (WGAN, SNGAN)

GANS

イロト イ団ト イヨト イヨト

Some major trends in the research

- Regularize and smooth the discriminator, especially in some region around the real and generated points
- Update the players towards some sort of consensus or future stable region, not just the immediate greedy update
- Simplify networks and losses to eliminate nonlinearities
- Constrain the "complexity" of the discriminator so you can train reliably without overtraining
- Grow or chain GANs to reduce complexity, learn a curriculum

Image: A mathematical states and a mathem

Where is current research?

Current techniques have impressive results

- Lots of GPUs and tuning required
- But the results are constantly improving
- Better techniques allow larger models, always pushing the limits
- Mostly images but other modalities are in-progress

Where is this going?

Ultimately, discriminator is calculating a divergence/loss function

- Neural networks are universal function approximators
- Loss functions are functions
- How can we measure/constrain the "complexity" of a neural network?
- How can we architect a neural network to learn a meaningful loss function?
